SUMMARY
Diabetes is a chronic disease that occurs when the pancreas does not produce enough insulin or when the body cannot effectively use the insulin it produces. This study was conducted to investigate the relationship between genetic polymorphism in adiponectin gene and the incidence of Type-II diabetes mellitus (T2DM) in a sample of Iraqi patients. Genetic polymorphism was studied in the variation site rs2241766 of adiponectin gene (ADIPOQ) located on the long arm of chromosome three (3q27), which regarded as a risk factor for the incidence of T2DM. First of all, genomic DNA was extracted from blood samples for T2DM patients and healthy controls with a concentration ranged between 200-400 µg/ml and purity ranged between 1.5-2.0, then exon 2 of ADIPOQ was amplified using specific primers. Results of electrophoresis on 2% agarose gel for the amplified products showed that there is an amplified fragment with a molecular size 372 bp was obtained. Results of sequencing for the amplified fragment showed that 60% of healthy controls are (TT) non-polymorphic in the site of variation of exon 2 when aligned with the reference sequence in NCBI data base, while it was found that 40% of healthy controls are polymorphic heterozygous (TG) in the same site. Results also showed that 67.6% of T2DM patients are (TT) non-polymorphic in the same site of ADIPOQ exon 2, while 33.3% of those patients were polymorphic heterozygous (TG), and there is no significant difference between the homozygous variations in both groups of healthy controls and T2DM patients which refers that this polymorphism was not regarded as a risk factor for the incidence of T2DM in Iraqi patients under study.
KEYWORDS: The metabolic syndrome, ADIPOQ, polymorphism, Type-II diabetes mellitus, case-control study, Iraq.

INTRODUCTION
Diabetes is a chronic disease that occurs when the pancreas does not produce enough insulin or when the body cannot effectively use the insulin it produces. Hyperglycemia, or increase in blood sugar, is a common effect of uncontrolled diabetes and over time it leads to serious damage to many of the body system, especially the nerves and blood vessel. During the last years the prevalence of diabetes has increased dramatically in many parts of the world and the disease is now a worldwide public health problem. The total number of people with diabetes is projected to rise from 171 million in 2000 to 366 million in 2030. There are three main types of DM are recognized Type1 DM or insulin depended diabetes mellitus (IDDM), Type2 DM or non-insulin depended diabetes mellitus (NIDDM) and Gestational Diabetes Mellitus (GDM). Other specific types of diabetes are caused by specific genetic defects of β-cells function or insulin action, the pancreas diseases and drug or chemical also induced diabetes mellitus.

Type-II diabetes is the result of failure to produce sufficient insulin and insulin resistance. Elevated blood glucose levels are managed with reduced food intake, increased physical activity, and eventually oral medications or insulin. Type-II diabetes is caused by a combination of genetic factors related to impaired insulin secretion and insulin resistance and environmental factors such as obesity, overeating, lack of exercise, and stress, as well as aging. It is typically a multifactorial disease involving multiple genes and environmental factors to varying extents.

Adipose tissue was considered to play an important role in the pathogenesis of diabetes, as well as obesity by secreting a variety of secretory proteins. Adiponectin is one of the major adipocyte secretory proteins most abundantly found in human plasma, with potent roles in insulin sensitivity in muscle and liver, regulating energy homeostasis and glucose tolerance. Adiponectin is a product of the ADIPOQ gene, which is located on human chromosome 3q27 that modulates a number of metabolic processes, including glucose regulation and fatty acid oxidation.

Many single nucleotide polymorphisms (SNPs) have been detected in ADIPOQ gene, which are associated with a variety of disorders. Most of the disorders are part of metabolic
syndromes e.g. impaired glucose tolerance, obesity, dyslipidemia and T2DM. The association of SNP +45 T > G in the adiponectin gene with Type-II diabetes and insulin resistance has been investigated in several populations.\textsuperscript{[10]} According to those findings, this study was aimed to determine the relationship between the genetic polymorphism and in ADIPOQ and the incidence of T2DM in a sample of Iraqi patients.

MATERIALS AND METHODS

Subjects
Venous blood was obtained after overnight fasting, and processed at the National Diabetes Center, Al-Mustansirya University in Baghdad governorate, in the period between October 2016 and November 2016.

Extraction of Genomic DNA
Total genomic DNA was extracted from 15 blood samples collected from T2DM patients, and from 15 blood samples collected from healthy volunteers. DNA extraction was carried out by using G-spin™ Blood gDNA silica membrane system supplied by iNtRON Biotechnology/KOREA.

Genotyping of the ADIPOQ +45 T > G polymorphism
The ADIPOQ +45 T > G polymorphism (rs2241766) was genotyped by polymerase chain reaction (PCR). The polymorphism was amplified using the following primers (11): forward, 5’-GCAGCTCATAGAAGTAGACTCTGCTG-3’ and reverse, 5’-GCAGGTCTGTGATGAAAGAGGCC-3’. Polymerase chain reaction was performed in a total volume of 25μl mixture containing 1.5μl DNA, 10μl forward primer, 10μl reverse primer, 5μl deoxynucleotide triphosphate (dNTP), 5 μl MgCl2, 16.5μl molecular biology grade D.W., 5μl of Taq DNA polymerase and 16.5 μl of ddH2O. The amplification conditions were as follows: 94 for 3 min, followed by 35 cycles of 40 sec. at 94, 1 min at 62 °C and 1 min at 72, and ending with a single 7 min extension step at 72. The PCR products were run on 2% agarose gels electrophoresis and viewed under an UV transilluminator to evaluate overall amplification efficiency.

Amplification products for exon 3 of ADIPOQ gene was sequenced, then sequences of these products was compared with the information in gene bank of the National Center for Biotechnology Information (NCBI) for standard ADIPOQ gene, using Bioedit software.
Statistical analysis
Continuous variables are presented as means ± standard deviation (SD) and difference between the cases and controls was compared using Student’s t-test for normally distributed variables or non-parametric Mann-Whitney U test for non-normally-distributed ones. Test for Hardy Weinberg equilibrium and comparison of allele and genotype distribution between MS cases and controls were assessed by chi-square test. Odds ratios (OR) and their 95% confidence intervals (CI) were calculated using the Mantel-Haenszel method. Multiple logistic regression analysis was performed to estimate an association of the +45 T > G polymorphism with the risk of MS. A p value less than 0.05 was considered statistically significant. All data analyses were performed using SAS version 9.2 software (SAS Institute Inc., Cary, NC, USA).

RESULTS AND DISCUSSION
Demographic characteristics of 15 T2DM patients and 15 controls are shown in Table 1. Mean age of the cases and controls were 58.65±1.10 years and 41.4±2.27 years, respectively.

Genomic DNA was first extracted from blood samples of T2DM patients and healthy controls. Results illustrated in figure (1) showed the clear bands for genomic DNA extracted from each blood samples with a concentration ranged between 200 and 400 ng/µl, while the purity was ranged between 1.5 and 2.0. This purity and concentration were suitable and recommended for further genetic analysis by using PCR technique. Polymerase chain reaction was used to amplify exon 2 of ADIPOQ in the extracted genomic DNA under the optimum amplification conditions by using specific primers shown previously.

Sequencing of Amplified Exon 2 of \textit{ADIPOQ} gene

In order to study the association of genetic polymorphism in \textit{ADIPOQ} (rs2241766) with susceptibility to T2DM in Iraqi population, PCR products for exon 2 were sequenced. Results illustrated in figure (2) showed the complete nucleotide sequence of this exon in healthy controls and T2D patients and the position of the expected SNP rs2241766 that may be associated with the incidence of the disease were defined.

\textbf{Figure (2):} Nucleotide sequences and amino acid of \textit{ADIPOQ} gene of exon 2. Yellow letter indicates the position of expected \textit{ADIPOQ} SNP in T2DM patients in Iraq. A: Sequence from healthy controls group, B: Sequence from T2DM patients group.

Alignment of amplified Exon 2 of \textit{ADIPOQ} Gene

Results illustrated figure (3) showed that the nucleotide sequence for \textit{ADIPOQ} exon 2 in healthy controls and it was found that only 9 (60\%) out of 15 controls were genotyped as non-polymorphic homozygous TT in comparison with reference sequence of NCBI, and was given ID: NG 021140.1 from 15320-15620 number of nucleotide from \textit{Homo sapiens} adiponectin gene, with score 556 and expect 155. This indicates that there is a high degree of similarity between both sequences which give greater confidence, while the other six healthy controls (40\%) genotyped as polymorphic heterozygous (TG), where thymine was substituted.
with guanine in the site of variation rs2241766 of ADIPOQ gene exon 2 as illustrated in figure (4).

Figure (3): A representative sequence alignment of ADIPOQ gene of exon 2 of non-polymorphic healthy controls (sbjct) aligned with reference sequence (Query) of ADIPOQ gene exon 2 obtained from Gene Bank. Yellow letters indicate the position of expected SNP.

Figure (4): A representative sequence alignment of ADIPOQ gene of exon 2 of polymorphic heterozygous T2DM patient (sbjct) compared with reference sequence (Query) of ADIPOQ gene exon 2, obtained from Gene Bank. Yellow letters indicate the position of expected SNP.
These results agree with other study who found that the frequency of TT and TG genotypes were 70.4% and 25.9% in healthy controls respectively, while the other GG are 3.7% in Han Chinese population.[11]

Results of nucleotide sequence for ADIPOQ exon 2 in Iraqi patients with T2DM illustrated in figure (5) showed that 10 (66.66%) out of 15 patients were genotyped as non-polymorphic homozygous TT and not significantly difference with healthy controls, Thymine nucleotide was located in the same position as in healthy controls without any base substitution to other nucleotides compared to reference sequence in this sample of patients.

This study showed that the ADIPOQ +45 T > G polymorphism was independently associated with T2DM. Type-II DM is due primarily to lifestyle factors and genetics. Type-II is the most common form of diabetes and is characterized by disorders of insulin action and insulin secretion. A number of lifestyle factors are known to be important to the development of Type-II DM. These are physical inactivity, sedentary lifestyle, cigarette smoking and generous consumption of alcohol. Obesity has been found to contribute to approximately 55% of cases of T2DM. The increased rate of childhood obesity is believed to have led to the increase in T2DM in children and adolescents. Environmental toxins may contribute to the recent increases in the rate of T2DM. A weak positive correlation has been found between the concentration in the urine of bisphenol A, a constituent of some plastics, and the incidence of T2DM. As shown in table (2), frequencies of TT, TG and GG genotypes were 66.66%, 33.33% and 0.00% in the patients, and 60%, 40% and 0.00% in the controls, respectively. There was no significant difference in distribution of the TT and TG genotypic frequencies between patients and controls. According to these results the homozygous TT genotype considered as predominant genotype within the population of this study and the presence of
TG genotype in control samples reveal that it has no effect on the disease occurrence. The absence of GG genotype considered it as infrequent genotype within the studied group. This study showed that the ADIPOQ +45 T > G polymorphism was independently associated with T2DM. Both genetic and environmental factors contribute to the development of MS.\textsuperscript{[15,16]} Some studies have provided evidence that the ADIPOQ +45 T>G polymorphism is associated with MS components.\textsuperscript{[17-19]} Both genetic and environmental factors contribute to the development of MS.\textsuperscript{27,28} Some studies have provided evidence that the ADIPOQ +45 T>G polymorphism is associated with MS components.\textsuperscript{[15-17]} However, a number of studies have mainly focused on the association of the polymorphism with one or two components of MS, such as obesity or/and T2DM.
